

Instructions: Please answer the following questions making sure to write your answers legibly on the second page. The code below is a segment of a Python application that provides context for the questions below.

- Since we are writing Python code, please be careful about spacing/indentation. Leave enough room that it is obvious when you want things indented.
- Make sure to write legibly.
- All questions are worth equal points unless otherwise stated.
- The quiz is cumulative and may include material from previous weeks.

compute.py

```
from utils import (
    clean_data,
    format_output,
    validate_params
)

def add_values(x, y):
    return x + y

def multiply_values(x, y):
    return x * y

def triple(n):
    return n * 3

def halve(n):
    return n / 2

def negate(n):
    return -n

if __name__ == '__main__':
    result = multiply_values(4, 7)
    print(f"Result: {result}")
```

1. Please write a function called `transform_all` that:

- Takes two arguments: `x` (a value) and `operations` (a list of functions)
- Applies each function in `operations` to `x`
- Returns a list of results from applying each function to `x`

For example: `transform_all(6, [triple, halve, negate])` should return `[18, 3.0, -6]`.

2. Please rewrite the function `multiply_values` so that when you enter `print(multiply_values.__doc__)` in Python, it returns the text: `Multiplies two values together`.

3. Please write a function called `display_info` that accepts any number and type of keyword arguments (but no positional arguments) and prints each key-value pair in the format: `"{key}: {value}"` (one per line). If the value is a string, instead print: `"{key}: Text"`.

4. [4 Points] In class we discussed how code complexity can be broken down into two categories: *essential* complexity and *accidental* complexity. Please list two sources of accidental code complexity.
